

1. FP Growth
2. Scanning DB and counting frequencies of occurrences of every object in say transactions. Prune those with less support level than minimum one. Then reorganize them by frequency

## FP Growth (Frequent Pattern-Growth Strategy)

- Suffix trees (trie) construction with respect support

*Помощь*

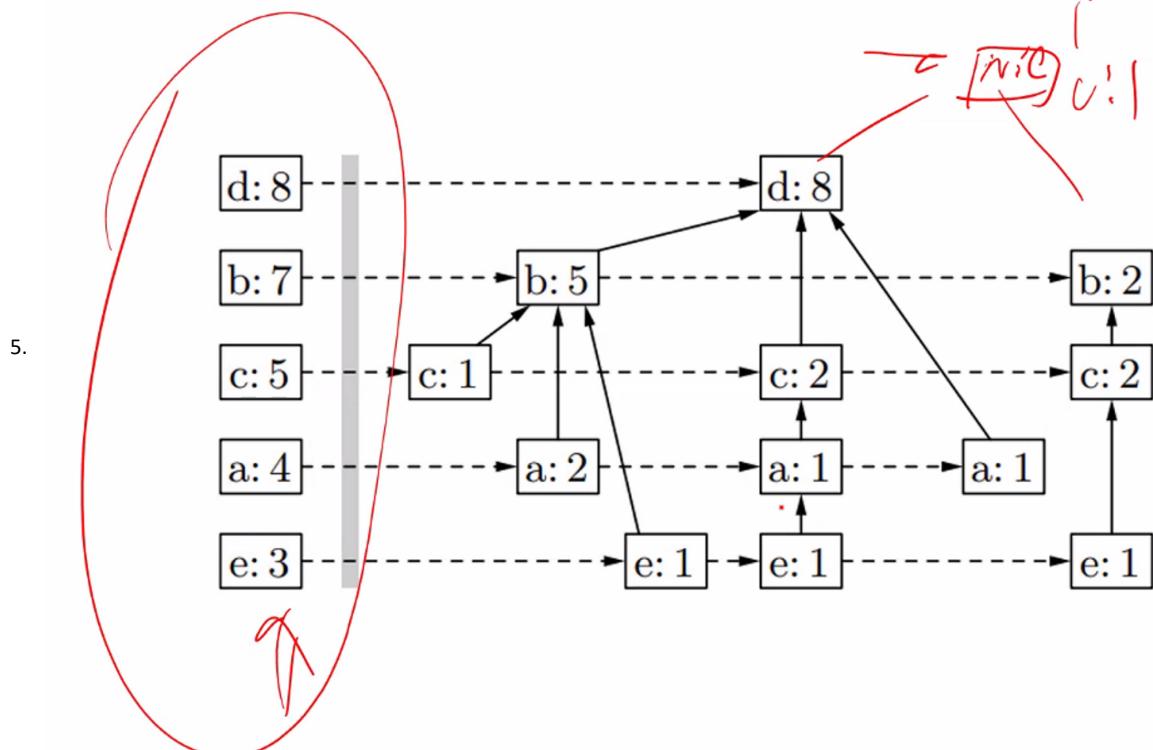

- a d f
- a c d e
- b d
3. b c d
- b c
- a b d
- b d e
- b c e g
- c d f
- a b d

d	8
b	7
c	5
a	4
e	3
f	2
g	1

- d a
- d c a e
- d b
- d b c
- b c
- d b a
- d b e
- b c e
- d c
- d b a

4. FP tree. Assigning frequencies while building

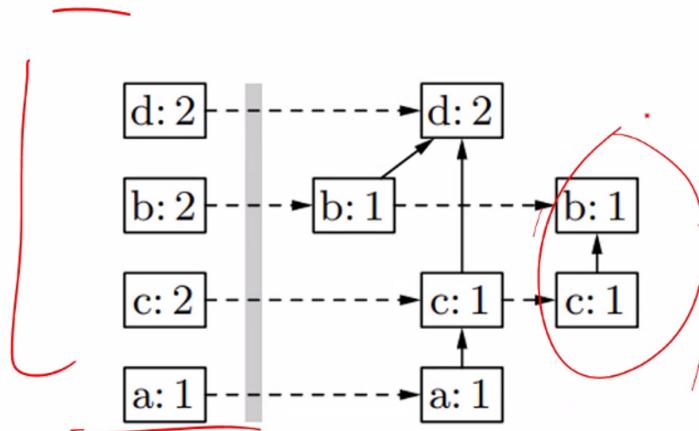

## FP Growth: Suffix tree

6. Haven't caught the slide, but the idea is that we are building the projection from bottom to up from the object we want to imply. In next picture there is a projection of rules that implies e. Frequencies are reassigned

## Patterns generation

1.

Let min support to be 2 transactions (it was 3, but I'm lazy to redraw picture 😊):

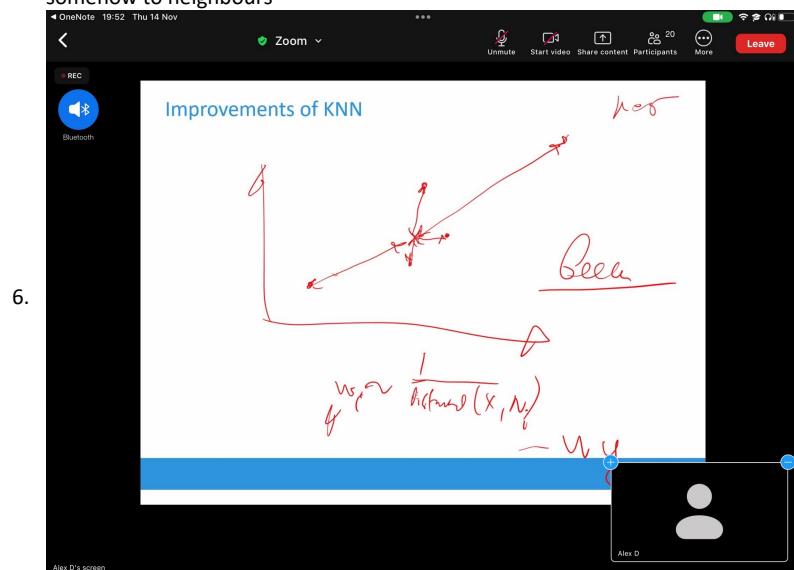

$d \rightarrow e$   
 $b \rightarrow e$   
 $c \rightarrow e$

# FP Growth vs Apriori

FP Growth	Apriori
<b>Pattern Generation</b>	
FP growth generates pattern by constructing a FP tree	Apriori generates pattern by pairing the items into singletons, pairs and triplets.
<b>Candidate Generation</b>	
There is no candidate generation	Apriori uses candidate generation
<b>Process</b>	
The process is faster as compared to Apriori. The runtime of process increases linearly with increase in number of itemsets.	The process is comparatively slower than FP Growth, the runtime increases exponentially with increase in number of itemsets
<b>Memory Usage</b>	
A compact version of database is saved	The candidates combinations are saved in memory

3. Classification. KNN - k neighbours
4. On a map of features looking for k neighbours and deciding what class does it belong to. If it's neighbour is cat, than it moves like cat and walks like cat than it is a 
5. But some neighbours can be closer than others, so it is vital to consider assigning weight somehow to neighbours

- 6.
7. But how it learns?
8. Very often it doesn't really learn. Lazy learner strategy just seek for k neighbours. But sometimes search trees are used for more efficient search of closest k neighbours

10. Linear regression

11. Prediction or classification is based on some linear equation.

## Linear Regression

- Used to estimate a continuous value as a linear (additive) function of other variables
  - ▶ Income as a function of years of education, age, and gender
  - ▶ House sales price as function of square footage, number of bedrooms/bathrooms, and lot size
- 12. • Outcome variable is continuous.
- Input variables can be continuous or discrete.
- Model Output:
  - ▶ A set of estimated coefficients that indicate the relative impact of each input variable on the outcome
  - ▶ A linear expression for estimating the outcome as a function of input variables

## Linear Regression Model

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p + \varepsilon$$

where  $y$  is the outcome variable

13.

$x_j$  are the input variables, for  $j = 1, 2, \dots, p$

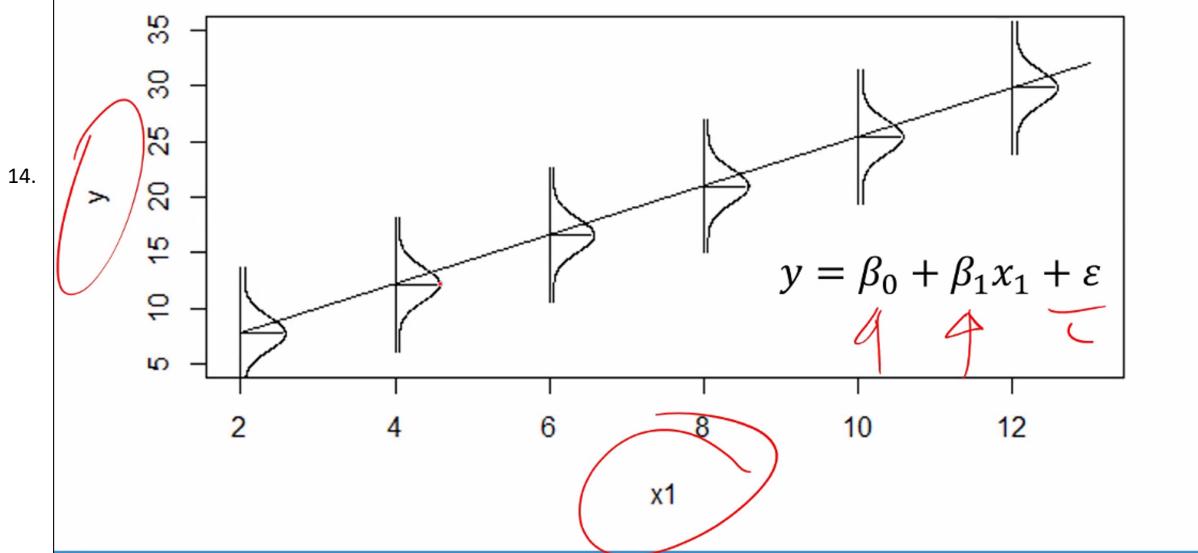

$\beta_0$  is the value of  $y$  when each  $x_j$  equals zero

$\beta_j$  is the change in  $y$  based on a unit change in  $x_j$

$\varepsilon \sim N(0, \sigma^2)$  and the  $\varepsilon$ 's are independent of each other

### Example: Linear Regression with One Input Variable

- $x_1$  - the number of employees reporting to a manager
- $y$  - the hours per week spent in meetings by the manager

Classes are basically types of vector. For example,  $(8, 1, 0, 0)$  is a class of finance manager

## Representing Categorical Attributes

$$y = \beta_0 + \beta_1 employees + \beta_2 finance + \beta_3 mfg + \beta_4 sales + \varepsilon$$

1.

Possible Situation	Input Variables
Finance manager with 8 employees	(8,1,0,0)
Manufacturing manager with 8 employees	(8,0,1,0)
Sales manager with 8 employees	(8,0,0,1)
Engineering manager with 8 employees	(8,0,0,0)

- For a categorical attribute with  $m$  possible values
  - ▶ Add  $m-1$  binary (0/1) variables to the regression model
  - ▶ The remaining category is represented by setting the  $m-1$  binary variables equal to zero

---

## Линейная регрессия как задача оптимизации

2.

$$\min_Q \frac{1}{2m} \sum_i^m (h_Q(x^{(i)}) - y^{(i)})^2$$

~~J(Q)~~ ~~t~~

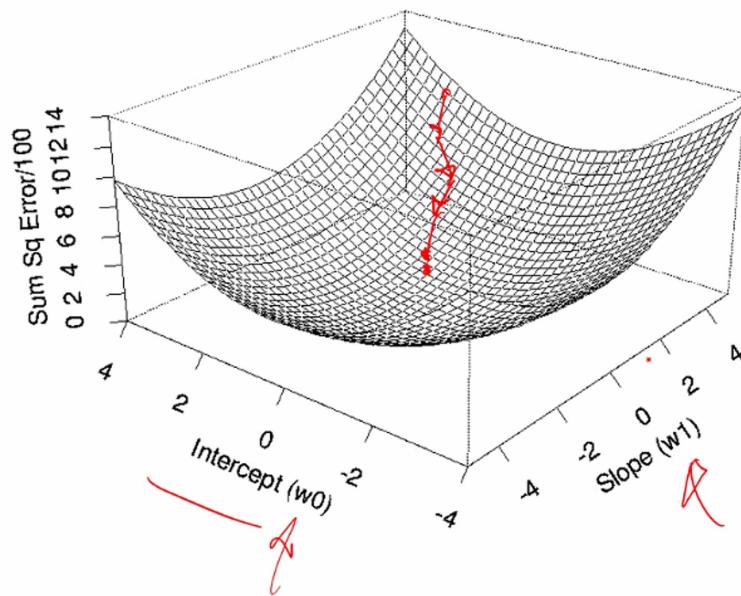

- квадратичная функция ошибки

$$J(Q) = \frac{1}{2m} \sum_i^m (h_Q(x^{(i)}) - y^{(i)})^2$$
$$\text{minimize } J(Q)$$

1. Moving towards anti-gradient, since gradient shows the vector of maximum increase

## Иллюстрация J(Q)

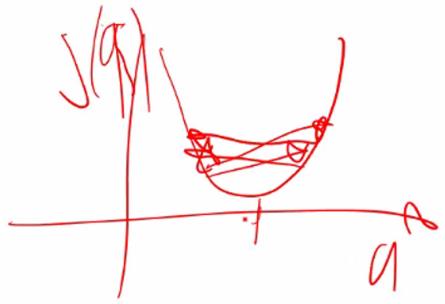

2.

## Алгоритм градиентного спуска (2)

```
while (|oldJ(Q) - J(Q)| > ε)
{
    oldJ(Q) = J(Q)
    Q₀ = Q₀ - λ / m ∑ᵢ  $m(h_Q(x^{(i)}) - y^{(i)})$ 
    Qₖ = Qₖ - λ / m ∑ᵢ  $m(h_Q(x^{(i)}) - y^{(i)}) x^{(i)}_k$ 
    foreach k=1...n
}
```

## Проблема выбора $\lambda$

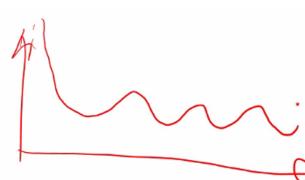

- $\lambda$  - малое
  - ▶ Медленная работа алгоритма
- $\lambda$  – большое
  - ▶ Плохое схождение алгоритма

4.

- Решение
  - ▶ Снижение темпа обучения ( $\lambda$ ) на каждом шаге

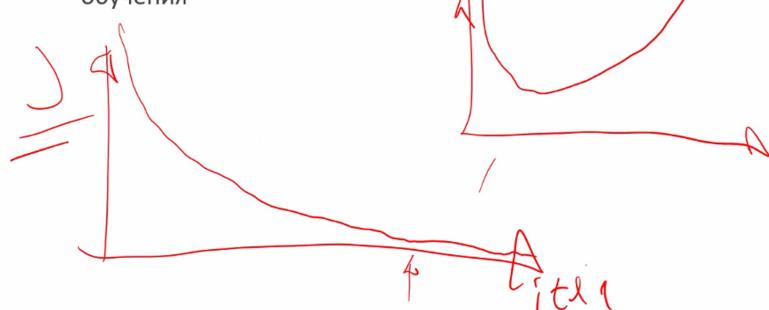

5. First picture - wrong lambda coefficient chosen, overthrowing. Second - wrong algo, third - good

### Диагностика

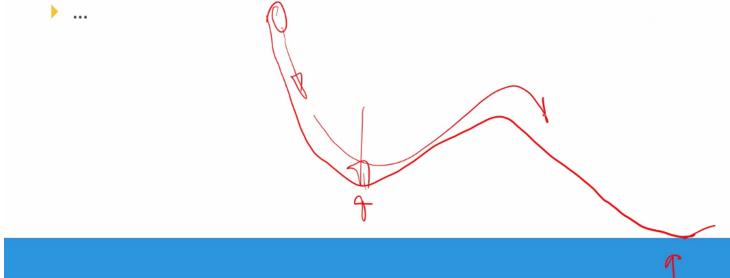

- Кривая обучения
  - ▶ Зависимость  $J(Q)$  от количества итераций
    - ▶ Должна уменьшаться, если алгоритм работает
    - ▶ Возрастающая – признак, что система не обучается
    - ▶ Колокол или периодичная – признак, что надо снизить темп обучения

6.

## Проблема локальных минимумов

- Решение
    - ▶ Использование более сложных алгоритмов ☺
  - Пример
    - ▶ Стохастический градиентный спуск
    - ▶ Метод имитации отжига (simulated annealing)
7. ▶ ...

Yey physics

## Имитация отжига

- Идея:
  - ▶ При высокой температуре более вероятны случайные переходы в другие состояния (можно «выпрыгнуть» из потенциальной ямы / локального минимума)
  - ▶ Температура постепенно снижается до 0
- 8. • Различные варианты
  - ▶  $\lambda(t)$  + градиентный спуск
  - ▶ Случайный переход  $\Delta(t)$ 
    - ▶ Со сравнением / без сравнения со старыми значениями
  - ▶ Градиентный спуск + случайный переход с вероятностью  $p(t)$

9. The more the temperature the highly likely are transitions to other states  
10. Also there is a problem of different scale. When variables are of very different scale. Then we can observe combe(ovrag in russian)  
11. The solution is normalization or rescaling

## Проблема переобучения

- Общая для машинного обучения
- Суть:
  - ▶ Можно обучить систему так, что она будет идеально работать на тренировочных данных, но не будет полезной моделью, т.к. не будет обладать классифицирующей или предсказательной способностью на данных, которые модель еще «не видела»
- 12. • Пример:
  - ▶ Чем выше степень полинома, тем более точно кривая пройдет, через базовые точки, но и тем более экстремально она будет себя вести
- 13. How to prevent?
- 14. Cut the number of input variables to only those that have the biggest impact. Others will only idealize the curve

## Регуляризация

- Идея:
  - ▶ Штрафовать модель за большие значения коэффициентов
- Два часто используемых подхода
  - ▶ Ridge (L2)
  - ▶ Lasso (L1)

15.

16. Logistic regression
